Abstract
This study aimed at investigating psychological health problems experienced by working women as a result of their experiences of intimate partner violence (IPV). One hundred one working women participated in the study. Results indicated that nearly half of the participants reported partner violence. Compared with nonabused women, abused women showed significantly higher levels of depressive symptoms (t (78) = -3.4, p = .001) and stress (t (93) = -4.8, p < .0001), while self-esteem did not differ significantly between the two groups. Acknowledgment of this problem and early recognition of the victims may result in improving the health of working women in Jordan.
